

## CLAIMS

The following is claimed:

- 1        1.        A method of generating a boundary-scan description language file for  
2        an integrated circuit; comprising the steps of:  
3                creating a flat netlist that describes said integrated circuit, wherein said flat  
4        netlist comprises connectivity information regarding leaf cells within said integrated  
5        circuit;  
6                determining and storing a name provided for each joint test action group  
7        register located within said integrated circuit, from said created flat netlist;  
8                determining relationships between each joint test action group register located  
9        within said integrated circuit and at least one input/output pin located within said  
10       integrated circuit, from said created flat netlist, and storing a description of said  
11       relationships; and  
12               creating said boundary-scan description language file from said stored names  
13       of each joint test action group and said stored description of said relationship between  
14       said joint test action group register and said input/output pin.

10079337 022002

1           2.       The method of claim 1, wherein said step of creating a flat netlist  
2 further comprises the steps of:  
3           traversing at least one hierarchical netlist that describes portions of said  
4 integrated circuit, for at least one individual netlist that describes a logic portion of  
5 said integrated circuit; and  
6           combining connectivity information provided by said at least one individual  
7 netlist, resulting in said flat netlist.

1           3.       The method of claim 2, wherein said connectivity information  
2 comprises relationships between wires within said integrated circuit, said leaf cells  
3 located within said integrated circuit and input/output pins.

1           4.       The method of claim 2, wherein said joint test action group register  
2 names are stored in the same order discovered during said traversing step.

1           5.       The method of claim 2, further comprising the step of:  
2           traversing said at least one hierarchical netlist for at least one individual netlist  
3 that describes at least one pad located within said integrated circuit.

1           6.       The method of claim 5, wherein said step of traversing said at least  
2 one hierarchical netlist is started at a beginning of a boundary-scan line, and wherein  
3 said step of traversing is ended at an end of said boundary-scan line.

1           7.       The method of claim 1, wherein said joint test action group registers  
2       comprise a JO joint test action group register, a JT joint test action group register, and  
3       a JI joint test action group register.

1           8.       A system for generating a boundary-scan description language file for  
2       an integrated circuit, comprising:

3               means for creating a flat netlist that describes said integrated circuit, wherein  
4       said flat netlist comprises connectivity information regarding leaf cells within said  
5       integrated circuit;

6               means for determining and storing a name provided for each joint test action  
7       group register located within said integrated circuit, from said created flat netlist;

8               means for determining relationships between each joint test action group  
9       register located within said integrated circuit and at least one input/output pin located  
10      within said integrated circuit, from said created flat netlist, and for storing a  
11      description of said relationships; and

12              means for creating said boundary-scan description language file from said  
13      stored names of each joint test action group and said stored description of said  
14      relationship<sup>s</sup> between said <sup>each</sup> joint test action group register and said input/output pin.

1           9.       The system of claim 8, further comprising:

2               means for traversing at least one hierarchical netlist that describes portions of  
3       said integrated circuit, for at least one individual netlist that describes a logic portion  
4       of said integrated circuit; and

5               means for combining connectivity information provided by said at least one  
6       individual netlist, resulting in said flat netlist.

1           10.     The system of claim 9, wherein said connectivity information  
2     comprises relationships between wires within said integrated circuit, said leaf cells  
3     located within said integrated circuit and input/output pins.

1           11.     The system of claim 9, wherein said joint test action group register  
2     names are stored in the same order discovered during traversing.

1           12.     The system of claim 9, further comprising means for traversing said at  
2     least one hierarchical netlist for at least one individual netlist that describes at least  
3     one pad located within said integrated circuit.

1           13.     The system of claim 12, wherein said means for traversing said at least  
2     one hierarchical netlist begins traversing at a beginning of a boundary-scan line and  
3     ends traversing at an end of said boundary-scan line.

1           14.     The system of claim 8, wherein said joint test action group registers  
2     comprise a JO joint test action group register, a JT joint test action group register, and  
3     a JI joint test action group register.

15. A system for generating a boundary-scan description language file for  
an integrated circuit, comprising:  
a memory;  
software stored within said memory defining functions to be performed by  
said system; and  
a processor configured by said software to perform the steps of:  
creating a flat netlist that describes said integrated circuit, wherein said  
flat netlist comprises connectivity information regarding leaf cells within said  
integrated circuit;  
determining and storing a name provided for each joint test action  
group register located within said integrated circuit, from said created flat netlist;  
determining relationships between each joint test action group register  
located within said integrated circuit and at least one input/output pin located within  
said integrated circuit, from said created flat netlist, and storing a description of said  
relationships; and  
creating said boundary-scan description language file from said stored  
names of each joint test action group and said stored description of said relationship  
between said joint test action group register and said input/output pin.

16. The system of claim 15, wherein said step of creating a flat netlist  
further comprises the steps of said processor traversing at least one hierarchical netlist  
that describes portions of said integrated circuit, for at least one individual netlist that  
describes a logic portion of said integrated circuit, and said processor combining  
connectivity information provided by said at least one individual netlist, resulting in  
said flat netlist.

1           17.     The system of claim 16, wherein said connectivity information  
2     comprises relationships between wires within said integrated circuit, said leaf cells  
3     located within said integrated circuit and input/output pins.

1           18.     The system of claim 16, wherein said joint test action group register  
2     names are stored in the same order discovered during said traversing step.

1           19.     The system of claim 16, wherein said processor is further configured  
2     by said memory to perform the step of traversing said at least one hierarchical netlist  
3     for at least one individual netlist that describes at least one pad located within said  
4     integrated circuit.

1           20.     The system of claim 19, wherein said step of traversing said at least  
2     one hierarchical netlist is started at a beginning of a boundary-scan line, and wherein  
3     said step of traversing is ended at an end of said boundary-scan line.
